

Module: Autacoids  
Subject: Pharmacology  
Lecture:

Histamine

# *Autacoids-Histamine & Antihistamines-1 & 2*

*Dr Biswadeep Das*

*Associate Professor(Pharmacology)*

AIIMS Rishikesh

विश्वारोग्यं हि धर्मो नः

# *Autacoids-Overview*

- Histamine, serotonin, prostaglandins, & some vasoactive peptides belong to a group of compounds called **autacoids**
- They all have the **common feature of being formed by the tissues on which they act**; thus, **they function as local hormones**
- The word autacoid comes from the Greek:
  - **autos (self) &**
  - **akos(medicinal agent, or remedy)**
- The autacoids also differ from circulating hormones in that they are **produced by many tissues** rather than in specific endocrine glands

# *Histamine-Pharmacology*

- First autacoid to be discovered
- Synthesized in 1907
- Demonstrated to be a natural constituent of mammalian tissues(1927)
- Involved in inflammatory & anaphylactic reactions
- Local application causes redness, swelling, & edema mimicking a mild inflammatory reaction
- Large systemic doses leads to profound vascular changes similar to those seen after shock or anaphylaxis

# *Histamine-Pharmacology(contd.)*

- Histamine is a **chemical messenger** that **mediates a wide range of cellular responses**, including:
  - **Allergic and inflammatory reactions**
  - **Gastric acid secretion, &**
  - **Neurotransmission in parts of the brain**
- Histamine **has no clinical applications**, but
- Agents that interfere with the action of histamine (**antihistamines**) **have important therapeutic applications**

# Histamine-Biosynthesis

- Histamine occurs in plants as well as in animal tissues & is a component of some venoms & stinging secretions
- Biosynthesized in mammalian tissues
- Decarboxylation of the amino acid L-Histidine yields Histamine

# *Histamine-Storage*

- In mast cells, histamine(positively charged) is held by an acidic protein and heparin(negatively charged) within intracellular granules
- Stored in complex with:
  - Heparin
  - Chondroitin sulphate
  - Eosinophilic Chemotactic Factor
  - Neutrophilic Chemotactic Factor
  - Proteases

# Histamine-Degradation

- Degraded rapidly by oxidation to **imidazole acetic acid**
- Degraded rapidly by methylation to **N-methyl histamine**
- Very little histamine is excreted unchanged

# *Histamine-Conditions causing Release*

- Tissue Injury
- Allergic Reactions
- Drugs & other foreign compounds

# *Histamine-Conditions causing Release*

## ■ Tissue Injury

- Any physical (mechanical) or chemical agent that injures tissue, skin or mucosa are particularly sensitive to injury and will cause the immediate release of histamine from mast cells
- Chemical and mechanical mast cell injury causes degranulation & histamine release
- **Compound 48/80**, an experimental drug, selectively releases histamine from tissue mast cells by an exocytotic degranulation process requiring energy & calcium

# *Histamine-Conditions causing Release*

## ■ Allergic Reactions

- Exposure of an antigen to a previously sensitized(exposed) subject can immediately trigger allergic reactions
- If sensitized by IgE antibodies attached to their surface membranes, mast cells will degranulate when exposed to the appropriate antigen & release histamine, ATP and other mediators

# Histamine & Allergic Reaction

Ricki Lewis, *Life*, 3e. Copyright © 1998 The McGraw-Hill Companies, Inc. All rights reserved.

## An Allergic Reaction — Overview

# *Histamine-Conditions causing Release(contd.)*

## ■ Drugs & other foreign compounds:

- Morphine/Dextran/Antimalarial drugs/Dyes/Antibiotic bases/Alkaloids/Amides/Quaternary ammonium compounds/Enzymes(PL-C)/Penicillins/Tetracyclines/Basic drugs(Amides/Amidines/Diamidines)/Toxins/Venoms/Proteolytic enzymes/Bradykin/Kallidin & Substance P
- Displace histamine from its bound form within cells
- This type of release does not require energy and is **not** associated with mast cell injury or degranulation

# *Histamine-Receptors*

- 4 Types of Histamine Receptors(all GPCR's):
  - H1 receptors:
    - Mediate effects on smooth muscle leading to vasodilation (relaxation of vascular smooth muscle), increased permeability & contraction of non-vascular smooth muscle
  - H2 receptors:
    - Mediate histamine stimulation of gastric acid secretion & may be involved in cardiac stimulation
  - H3 receptors:
    - Feedback inhibition in CNS, GIT, Lungs & Heart
  - H4 receptors:
    - Eosinophils, Neutrophils & CD4 T-cells

# *Histamine-Receptor Subtypes*

Receptor	Mechanism	Function	Antagonists
H1	Gq, ↑ IP3 & DAG	<ul style="list-style-type: none"><li>■ Ileum contraction</li><li>■ Modulate circadian cycle</li><li>■ Itching</li><li>■ Systemic vasodilatation</li><li>■ Bronchoconstriction</li></ul>	Diphenhydramine/Loratadine/Cetirizine/Fexofenadine
H2	Gs, ↑cAMP, ↑Ca <sup>2+</sup>	<ul style="list-style-type: none"><li>■ Speed up sinus rhythm</li><li>■ Stimulation of gastric secretion</li><li>■ Smooth muscle relaxation</li><li>■ Inhibit antibody synthesis, T-cell proliferation &amp; cytokine production</li></ul>	Cimetidine/Ranitidine/Famotidine/Nizatidine

# Histamine-Receptor Subtypes

Receptor	Mechanism	Function	Antagonists
H3	Gi, ↓cAMP	<ul style="list-style-type: none"><li>■ Decrease Acetylcholine, Serotonin and Norepinephrine neurotransmitter release in the CNS</li><li>■ Presynaptic autoreceptors</li></ul>	ABT-239/ Ciproxifan/ Clobenpropit/T hioperamide
H4	Gi, ↓cAMP	<ul style="list-style-type: none"><li>■ Mediate mast cell chemotaxis</li></ul>	Thioperamide/ JNJ 7777120

# Histamine-Pharmacological Actions(H1)

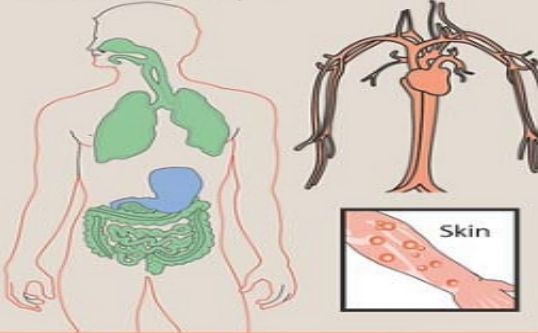

**H<sub>1</sub> Receptors**

**EXOCRINE EXCRETION**  
Increased production of nasal and bronchial mucus, resulting in respiratory symptoms.

**BRONCHIAL SMOOTH MUSCLE**  
Constriction of bronchioles results in symptoms of asthma and decreased lung capacity.

**INTESTINAL SMOOTH MUSCLE**  
Constriction results in intestinal cramps and diarrhea.

**SENSORY NERVE ENDINGS**  
Causes itching and pain.

**H<sub>1</sub> and H<sub>2</sub> Receptors**

**CARDIOVASCULAR SYSTEM**  
Lowers systemic blood pressure by reducing peripheral resistance. Causes positive chronotropism (mediated by H<sub>2</sub> receptors) and a positive inotropism (mediated by both H<sub>1</sub> and H<sub>2</sub> receptors).

**SKIN**  
Dilation and increased permeability of the capillaries results in leakage of proteins and fluid into the tissues. In the skin, this results in the classic "triple response": wheal formation, reddening due to local vasodilation, and flare ("halo").

**H<sub>2</sub> Receptors**

**Stomach**  
Stimulation of gastric hydrochloric acid secretion.

- Exocrine Excretion(H1)
  - ↑ Production of nasal + bronchial mucus
- Bronchial Smooth Muscle(H1)
  - Bronchiolar constriction
  - Asthmatic symptoms
  - ↓ Lung capacity
- Intestinal Smooth Muscle(H1)
  - Contraction → Intestinal cramps & diarrhea
- Sensory Nerve Endings(H1)
  - Itching & pain

# Histamine-Pharmacological Actions(H1&2)

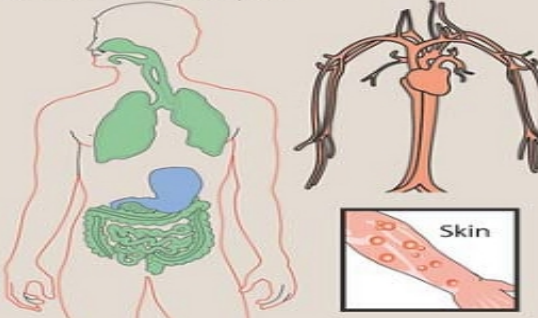

**H<sub>1</sub> Receptors**

**EXOCRINE EXCRETION**  
Increased production of nasal and bronchial mucus, resulting in respiratory symptoms.

**BRONCHIAL SMOOTH MUSCLE**  
Constriction of bronchioles results in symptoms of asthma and decreased lung capacity.

**INTESTINAL SMOOTH MUSCLE**  
Constriction results in intestinal cramps and diarrhea.

**SENSORY NERVE ENDINGS**  
Causes itching and pain.

**H<sub>1</sub> and H<sub>2</sub> Receptors**

**CARDIOVASCULAR SYSTEM**  
Lowers systemic blood pressure by reducing peripheral resistance. Causes positive chronotropism (mediated by H<sub>2</sub> receptors) and a positive inotropism (mediated by both H<sub>1</sub> and H<sub>2</sub> receptors).

**SKIN**  
Dilation and increased permeability of the capillaries results in leakage of proteins and fluid into the tissues. In the skin, this results in the classic "triple response": wheal formation, reddening due to local vasodilation, and flare ("halo").

**H<sub>2</sub> Receptors**

**Stomach**  
Stimulation of gastric hydrochloric acid secretion.

## ■ Cardiovascular System(H1&2)

- ↓ Peripheral resistance → ↓ Systemic BP
- +ve chronotropism(H2)
- +ve inotropism

## ■ Skin(H1&2)

- Dilatation & ↑ permeability of the venules
- Leakage of fluid + proteins into the tissues
- Classic "triple-response"(wheal formation+ reddening due to local VD(<1-2 min)+ flare(halo))

# Histamine-Pharmacological Actions(H2)

## ■ Stomach(H2)

- ↑ Gastric HCl secretion

### H<sub>1</sub> Receptors

#### EXOCRINE EXCRETION

Increased production of nasal and bronchial mucus, resulting in respiratory symptoms.

#### BRONCHIAL SMOOTH MUSCLE

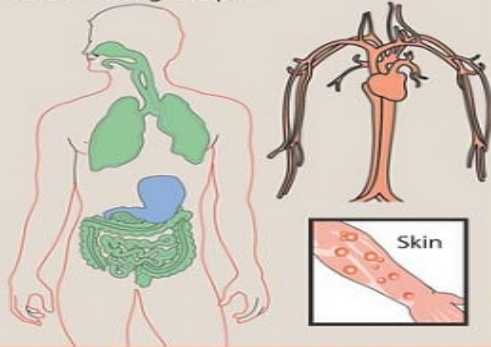

Constriction of bronchioles results in symptoms of asthma and decreased lung capacity.

#### INTESTINAL SMOOTH MUSCLE

Constriction results in intestinal cramps and diarrhea.

#### SENSORY NERVE ENDINGS

Causes itching and pain.

### H<sub>1</sub> and H<sub>2</sub> Receptors

#### CARDIOVASCULAR SYSTEM

Lowers systemic blood pressure by reducing peripheral resistance. Causes positive chronotropism (mediated by H<sub>2</sub> receptors) and a positive inotropism (mediated by both H<sub>1</sub> and H<sub>2</sub> receptors).

#### SKIN

Dilation and increased permeability of the capillaries results in leakage of proteins and fluid into the tissues. In the skin, this results in the classic "triple response": wheal formation, reddening due to local vasodilation, and flare ("halo").

### H<sub>2</sub> Receptors

#### Stomach

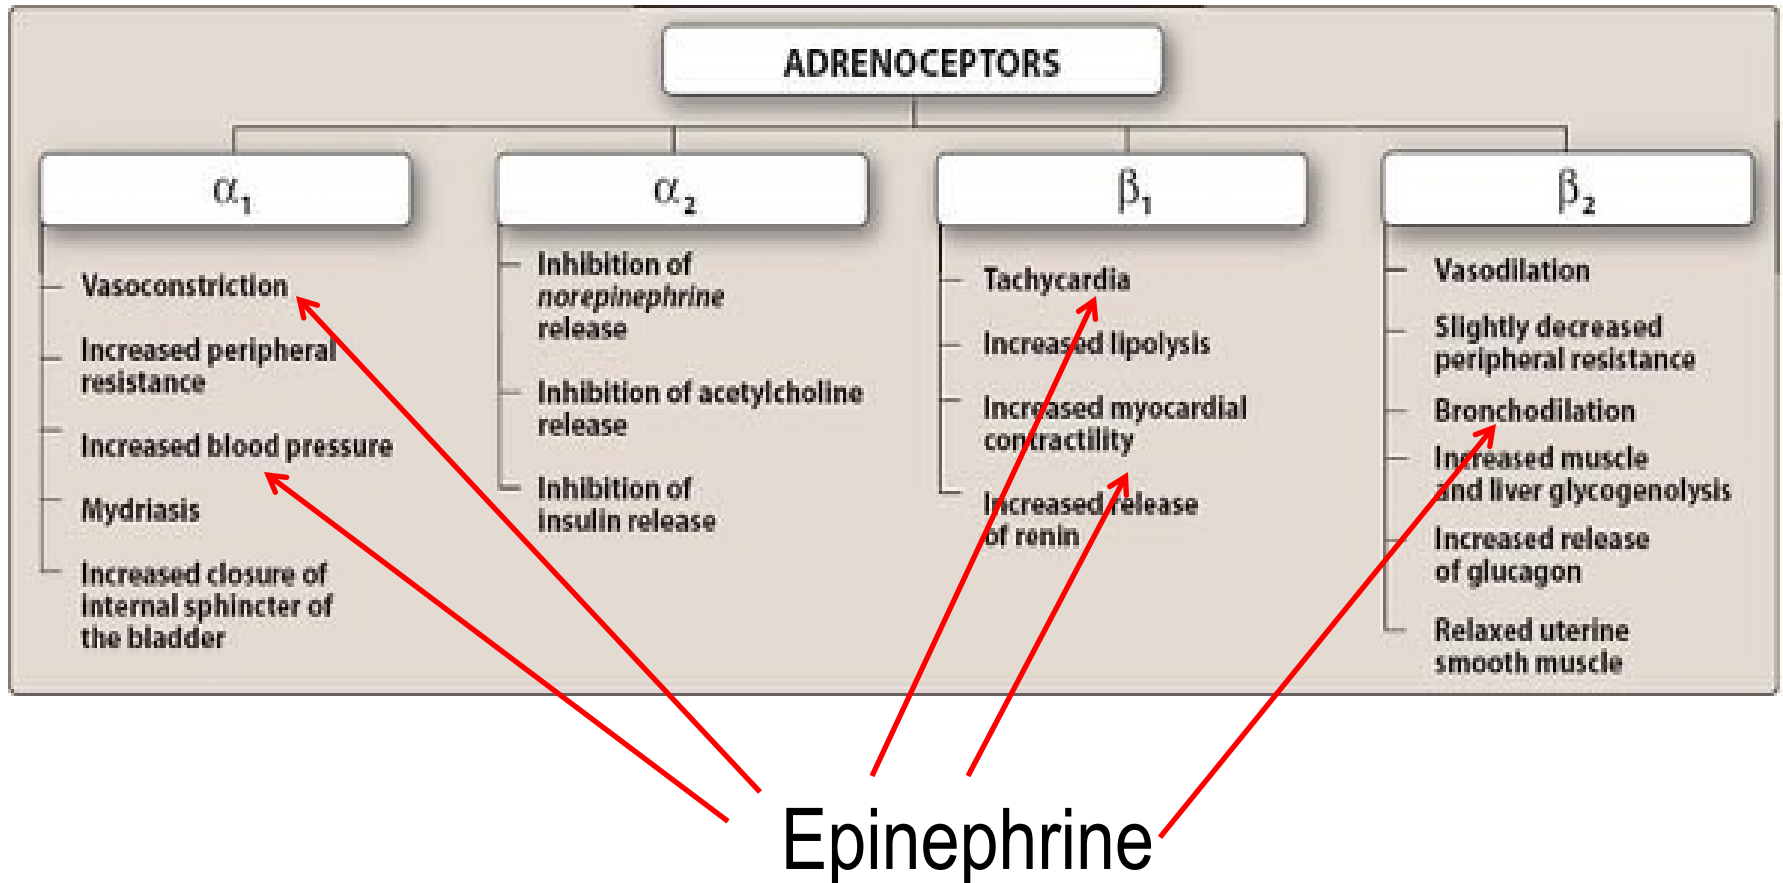

Stimulation of gastric hydrochloric acid secretion.

# *Histamine Antagonists*

- The effects of histamine released in the body can be reduced in several ways
- **Physiologic antagonists**, especially epinephrine, have smooth muscle actions opposite to those of histamine, by acting at different receptors
- This is important clinically because **injection of epinephrine can be lifesaving in systemic anaphylaxis**/other conditions in which massive release of histamine (and other more important mediators) occurs

# *Adrenoceptor Agonists (Sympathomimetics)- Major Effects Mediated By Alpha & Beta Adrenoceptors for Epinephrine in the Management of Anaphylaxis*

# *Adrenoceptor Agonists(Sympathomimetics)- Use of Epinephrine in Anaphylaxis*

## ■ Anaphylaxis

- **Epinephrine** is the **drug of choice** for the immediate treatment of anaphylactic shock
- It is **an effective physiologic antagonist** of many of the mediators of anaphylaxis
- Epinephrine is sometimes supplemented with **antihistamines and corticosteroids**, but these agents are **neither as efficacious as epinephrine** nor as rapid acting

# *Histamine Antagonists-Release Inhibitors*

- **Release inhibitors** reduce the degranulation of mast cells that results from immunologic triggering by antigen-IgE interaction
- **Cromolyn** and **nedocromil** appear to have this effect and have been used in the treatment of asthma, although the molecular mechanism underlying their action is not fully understood
- **Beta2-adrenoceptor agonists** also appear capable of reducing histamine release

# *Histamine Release Inhibitors- Therapeutic Uses*

- Mild to moderate bronchial asthma
  - To prevent acute attacks
  - Effective in children
  - Reduces need of steroids or bronchodilators
  - Ineffective for an acute attack
  - Becomes effective over time(e.g., 2-3 weeks)
- Allergic rhinitis
- Atopic diseases of the eye
- Giant papillary conjunctivitis

# *H1 Antihistamines-Overview*

- The term antihistamine, refers to the classic H1-receptor blockers
- These compounds do not influence the formation or release of histamine; rather, they block the receptor-mediated response of a target tissue
- This contrasts with the action of cromolyn & nedocromil, which inhibit the release of histamine from mast cells and are useful in the treatment of asthma

# H1 Antihistamines-2

## Generations

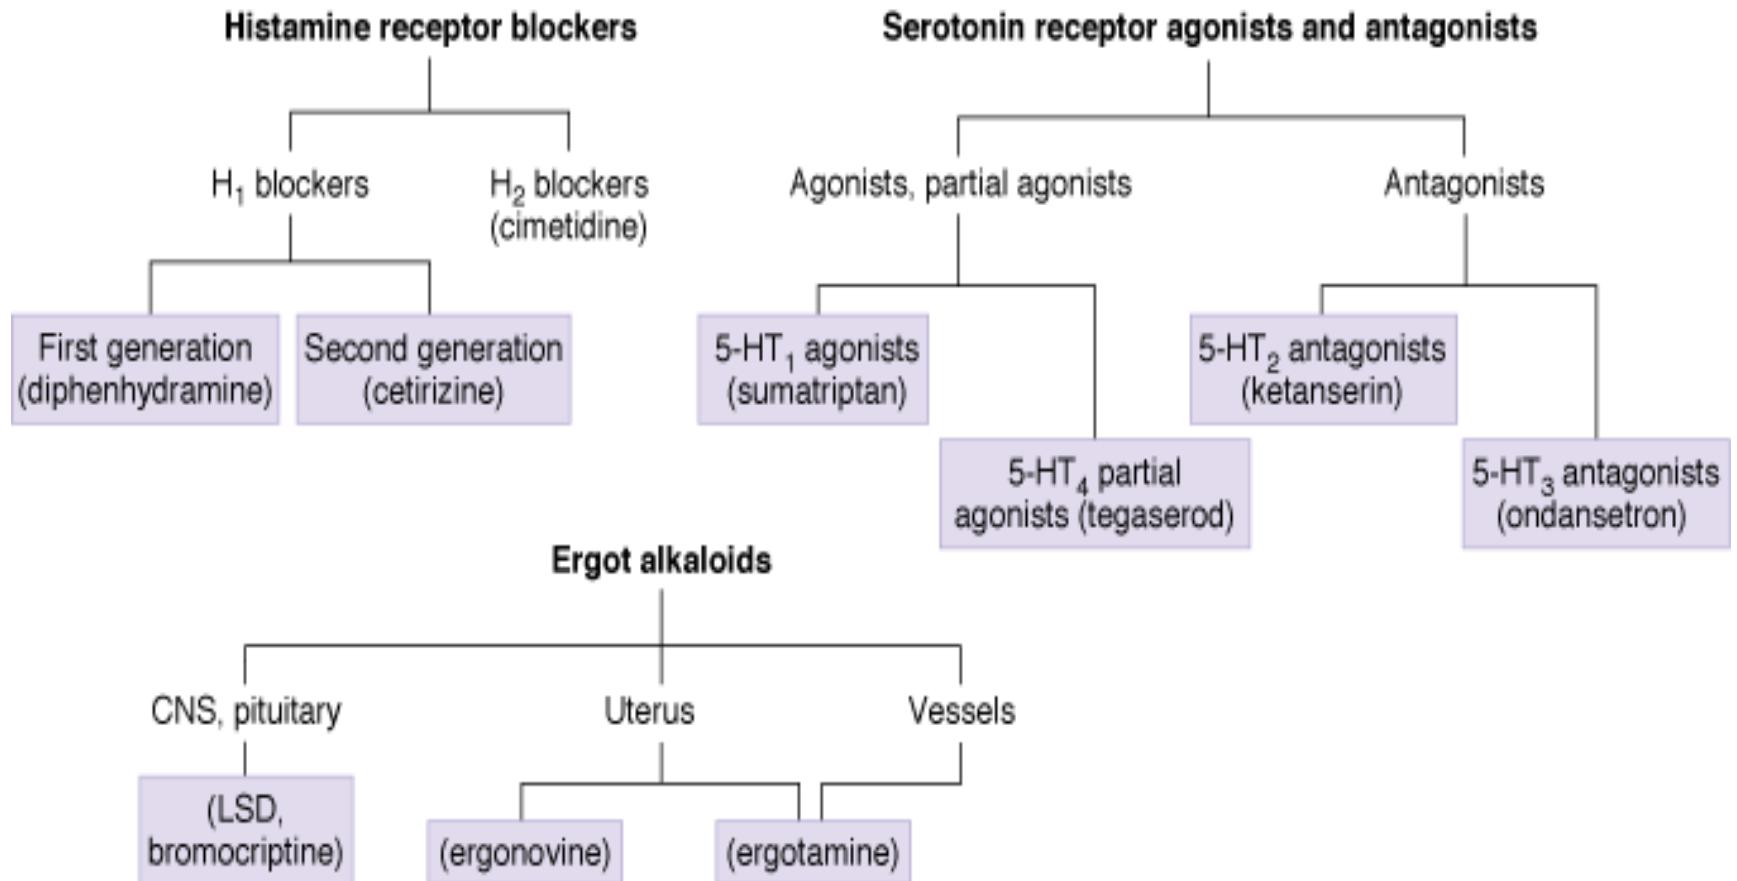

- The H1-receptor blockers can be divided into first- & second-generation drugs
- The older first-generation drugs are still widely used because they are effective and inexpensive
- However, most of these drugs penetrate the CNS and cause sedation

# H1 Antihistamines-2 Generations

- By contrast, the second-generation agents are specific for H1 receptors
- Because they do not penetrate the blood-brain barrier, they show less CNS toxicity than the first-generation drugs
- Among these agents loratadine/ desloratadine/ fexofenadine produce the least sedation

# Histamine Receptor Blockers- Classification

# General Structure of H<sub>1</sub> Antagonist Drugs & examples of the Major Subgroups

## ■ First Generation

### □ Alkylamines

- Pheniramine/Chlorpheniramine/Dexchlorphenamine/Brompheniramine/Tripolidine

### □ Ethanolamines

- Carbinoxamine/Clemastine/Diphenhydramine/Dimenhydrinate/Doxylamine

# General Structure of H<sub>1</sub> Antagonist Drugs & examples of the Major Subgroups

## ■ First Generation(contd.)

- Ethylenediamines
  - Antazoline/Mepyramine (Pyrilamine)
- Piperazines
  - Cyclizine/Chlorcyclizine /Hydroxyzine/Meclizine
- Tricyclics
  - Alimemazine(Trimeprazine)/Azatadine/ Cyproheptadine/ Ketotifen/Promethazine

# General Structure of H<sub>1</sub> Antagonist Drugs & examples of the Major Subgroups

## ■ Second Generation

- Acrivastine(modification of Triprolidine)
- Azelastine
- Cetirizine(Piperazine)
- Desloratadine(Piperidine)
- Fexofenadine(Piperidine)
- Loratadine(Piperidine)
- Levocabastine

# Antihistamines-Mechanism of Action(PD)

## ■ Actions

- The action of all the H<sub>1</sub>-receptor blockers is qualitatively similar(block action of histamine at H<sub>1</sub> receptors)
- However, most of these blockers have additional effects unrelated to their blocking of H<sub>1</sub> receptors
- These effects probably reflect binding of the H<sub>1</sub> antagonists to cholinergic, adrenergic, or serotonin receptors

# *Antihistamines-Mechanism of Action(PD)*

## ■ Sedation

- A common effect of first-generation H1 antagonists is sedation, but the intensity of this effect varies among chemical subgroups
- Second-generation H1 antagonists have little or no sedative or stimulant actions
- These drugs (or their active metabolites) also have far fewer autonomic effects than the first-generation antihistamines

# *Antihistamines-Mechanism of Action(PD)*

## ■ **Antinausea and Antiemetic Actions**

- Several first- generation H1 antagonists have significant activity in preventing motion sickness
- They are less effective against an episode of motion sickness already present

# *Antihistamines-Mechanism of Action(PD)*

## ■ Antiparkinsonian Effects

- H1 antagonists, especially **diphenhydramine**, have **significant acute suppressant effects on the EPS associated with certain antipsychotic drugs**
- Given parenterally for acute dystonic reactions to antipsychotics

# *Antihistamines-Mechanism of Action(PD)*

## ■ **Anticholinoceptor Actions**

- First-generation agents, especially those of **ethanolamine** and **ethylenediamine subgroups**, have significant **atropine-like effects** on peripheral muscarinic receptors
- Benefits reported for nonallergic rhinorrhea
- May also cause urinary retention and blurred vision

# *Antihistamines-Mechanism of Action(PD)*

## ■ Adrenoceptor-Blocking Actions

- Alpha-receptor blocking effects demonstrable for many H1 antagonists, especially phenothiazine subgroup, e.g., **promethazine**
- This action may cause orthostatic hypotension in susceptible individuals

# *Antihistamines-Mechanism of Action(PD)*

## ■ Serotonin-Blocking Action

- Strong **blocking effects at serotonin receptors** have been demonstrated for some first-generation H1 antagonists, notably **cyproheptadine**
- Its structure resembles that of the phenothiazine antihistamines, and it is a potent H1-blocking agent

# *Antihistamines-Mechanism of Action(PD)*

## ■ **Local Anesthesia**

- Several first-generation H1 antagonists are potent local anesthetics
- They **block sodium channels** in excitable membranes in the same fashion as procaine and lidocaine
- **Diphenhydramine and promethazine are actually more potent than procaine as local anesthetics**

# *Antihistamines-PK*

## ■ Absorption

- These agents are rapidly absorbed after oral administration
- Peak blood concentrations occur in 1–2 hours

## ■ Distribution

- Widely distributed throughout the body
- First-generation drugs enter CNS readily

## ■ Biotransformation(Metabolism)

- Some of them are extensively metabolized, primarily by microsomal systems in the liver
- Several of the second-generation agents are metabolized by the CYP3A4 system and thus are subject to important interactions when other drugs(such as ketoconazole) inhibit this subtype of P450 enzymes

## *Antihistamines-PK(contd.)*

- The newer agents are considerably less lipid-soluble than the first-generation drugs and are substrates of the P-glycoprotein transporter in the blood-brain barrier
- As a result they enter the CNS with difficulty or not at all
- Many H1 antagonists have active metabolites

# *Antihistamines-PK(contd.)*

Parent Drug	Active Metabolite	Available as Drug
Hydroxyzine	Cetirizine	Yes
Loratadine	Desloratadine	Yes
Terfenadine	Fexofenadine	Yes

## ■ Elimination

- Cetirizine is excreted largely unchanged in the urine, &
- Fexofenadine is excreted largely unchanged in the feces

# *Antihistamines-Therapeutic Uses*

- **Allergic and inflammatory conditions**
- H1-receptor blockers **useful in treating allergies** caused by antigens acting on immunoglobulin E antibody–sensitized mast cells
- Antihistamines are the **drugs of choice in controlling the symptoms of allergic rhinitis and urticaria**, because histamine is the principal mediator
- However, the H1-receptor blockers are **ineffective in treating bronchial asthma**, because histamine is only one of several mediators of that condition (**LTs are the main mediators**)

# *Antihistamines-Therapeutic Uses*

- **Motion sickness/Nausea:**
- Along with the antimuscarinic agent scopolamine, certain H<sub>1</sub>-receptor blockers, such as diphenhydramine, dimenhydrinate, cyclizine, meclizine, and hydroxyzine, are the most effective agents for prevention of the symptoms of motion sickness
- Prevent or diminish vomiting and nausea mediated by both the chemoreceptor and vestibular pathways
- The antiemetic action of these medications seems to be due to their blockade of central H<sub>1</sub> + muscarinic receptors

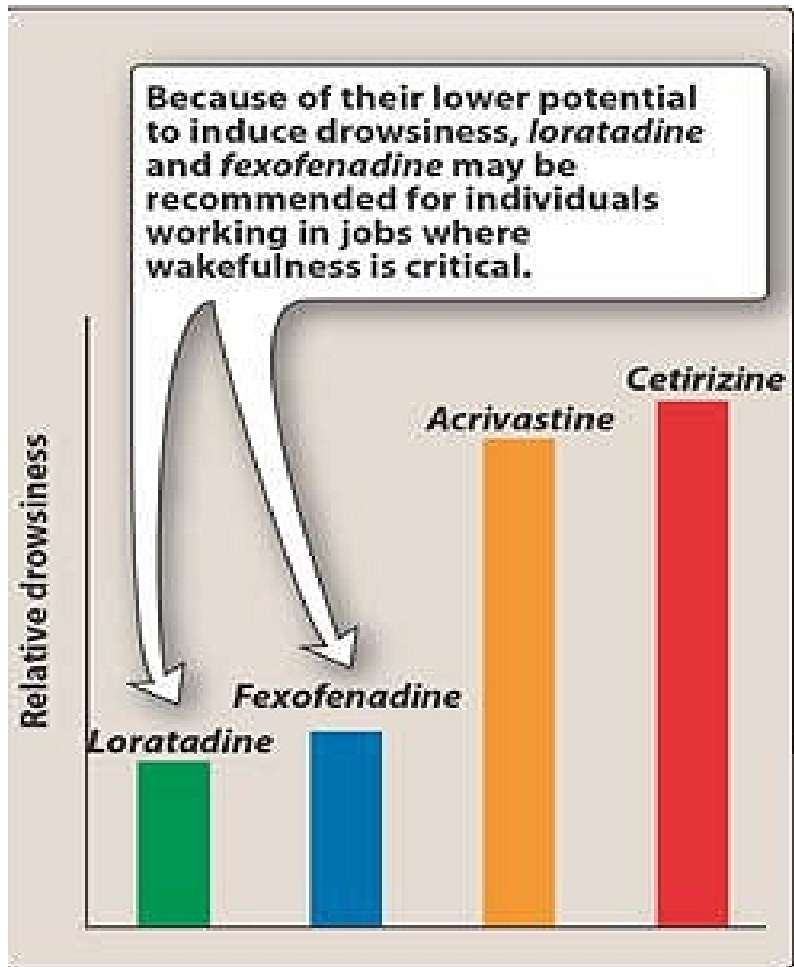

# *Antihistamines-Therapeutic Uses*

- **Somnifacients:**
- Although they are not the medication of choice, many first-generation antihistamines, such as diphenhydramine and doxylamine, have strong sedative properties and are used in the treatment of insomnia
- The use of first-generation H1 antihistamines is contraindicated in the treatment of individuals working in jobs where wakefulness is critical

# *Antihistamines-Therapeutic Uses*

- **Nausea and Vomiting of Pregnancy:**
- Several H1-antagonist drugs have been studied for possible use in treating "morning sickness"
- The **piperazine derivatives** were withdrawn from such use when it was demonstrated that they have **teratogenic effects in rodents**

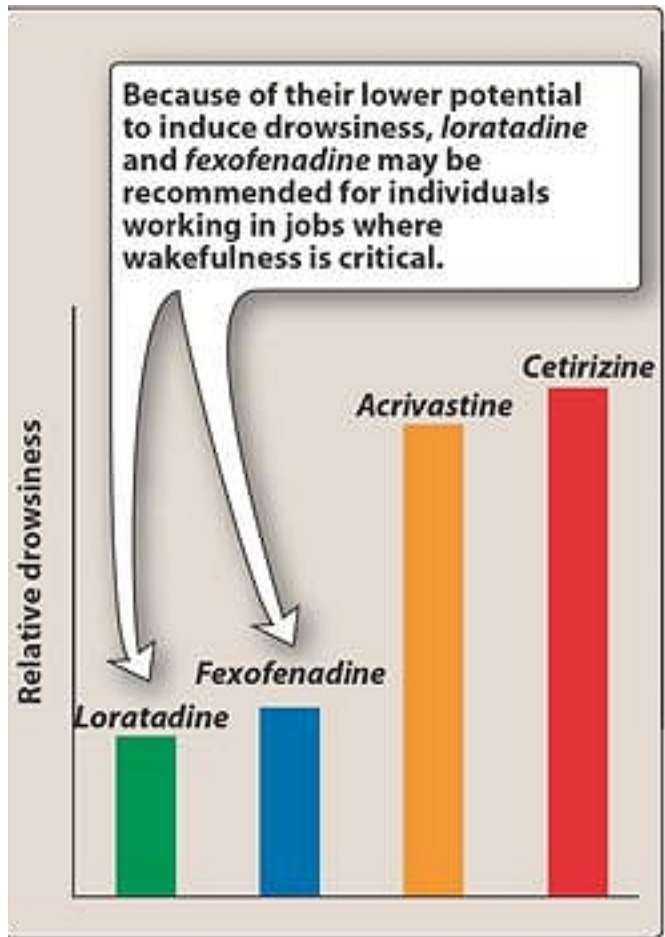

# Antihistamines-Adverse Effects & Toxicity

## ■ Sedation:

- First-generation H1 antihistamines, such as chlorpheniramine, diphenhydramine, hydroxyzine, and promethazine, bind to H1 receptors and block the neurotransmitter effect of histamine in the CNS
- The most frequently observed adverse reaction is sedation

# Antihistamines-Adverse Effects & Toxicity

## ■ Sedation:

- Sedation is less common with the second-generation drugs, which do not readily enter the CNS
- Second-generation H1 antihistamines are specific for H1 receptors and penetrate the CNS poorly
- They show less sedation and other CNS effects

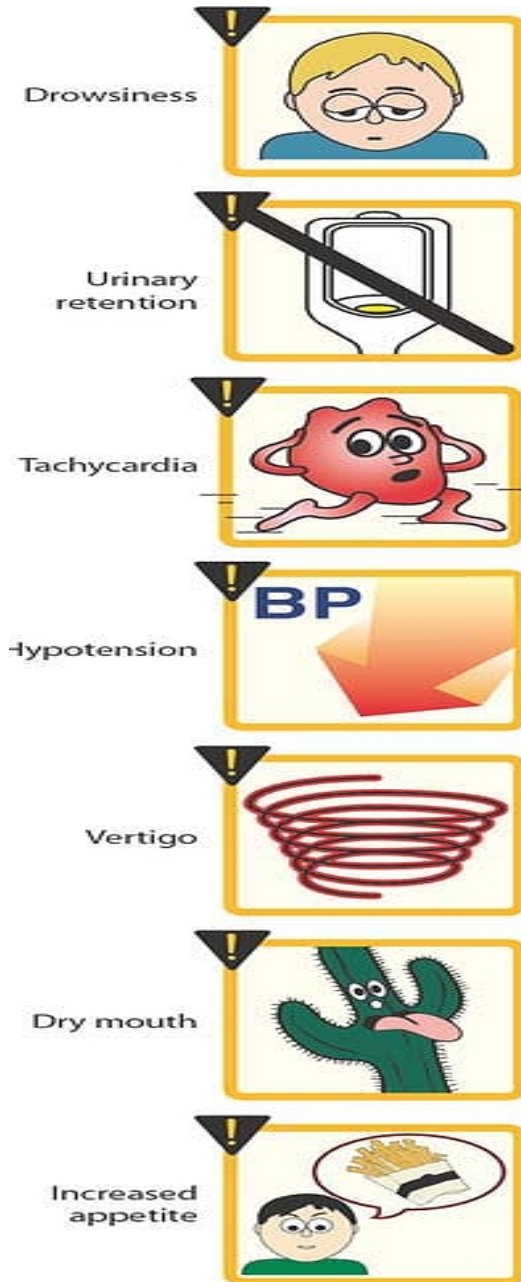

# *Antihistamines-Adverse Effects & Toxicity*

## ■ **Other CNS actions:**

- Other central actions include tinnitus, fatigue, dizziness, lassitude(a sense of weariness), incoordination, blurred vision, and tremors

# *Antihistamines-Adverse Effects & Toxicity*

## ■ Dry mouth:

- Oral antihistamines also exert **weak anticholinergic effects**, leading not only to a **drying of the nasal passage** but also to a tendency to **dry the oral cavity**
- Blurred vision** can occur as well with some drugs
